

UFRO 5722 NOISE SOURCE USER'S MANUAL

Dave Typinski, April, 2020

Description

The UFRO 5722 Noise Source is based on two Sylvania 5722 vacuum tube noise diodes operating in parallel. The unit has been modified by AJ4CO to eliminate the plate current sensing resistor and remote power supply controls as the original power supplies have been replaced with supplies that include accurate voltage and current meters. The circuit is much like that recommended by Sylvania. A schematic and tube tech data are included in this manual.

The assembly is built on one 3U (5¼" tall) 19" rack panel and requires two power sources:

Filament supply: 5.2 VDC at 3.1 A

Plate supply: 150 VDC at 70 mA

As installed at AJ4CO Observatory, the filament supply is a TTi PL155 power supply and the plate voltage is provided by a TTi PLH250 power supply.

In the Summer of 2012, the noise generator was salvaged from the Dixie Radio Observatory. In the Spring of 2013, it was found that the 5 VDC supply being used for the filament circuit could no longer deliver the required current—about 5 volts at 3.1 amps. In lieu of another 5 VDC supply, the noise generator panel was modified to include a 6.3 volt filament transformer driven by a small variac. That is, the filaments were then fed with ~ 5 VAC.

In June 2017, it was noticed that line voltage variations were causing a +/- 2 mA random oscillation in plate current. This is equivalent to +/- 0.12 dB in terms of noise power output. It was decided that a 0.25 dB uncertainty range was too large.

In May, 2018, the AC filament power circuit elements were removed and replaced by the TTi low voltage DC supply in May, 2018. The plate current sensing resistor was also removed, as the plate current reading on the new TTi plate supply was observed to be within 0.01 mA of that shown on a freshly-calibrated HP 34401A DVM connected in series. Ref circuit diagram Rev C.

In April, 2020, the 4700 pF output coupling cap was moved to the filament center tap of one of the tubes and the RF output was straight from the plates. Ref circuit diagram Rev D. A 0.1 μF coupling cap was added between the plate and RF output. Ref circuit diagram Rev E. The noise temperature output of circuit revisions C, D, and E were measured; no appreciable difference was observed. The noise generator was left in the Rev E state.

With 70 mA of plate current, the noise output is 20,600 K into a 50 ohm load.

Operation

Start up:

- 1) Connect power supplies, **note proper polarity: plate supply positive goes to ground.**
- 2) Feed 3.5 VDC to the filament circuit to put the tubes in standby mode. Best practice for tube type equipment is to always turn on the filaments before applying plate voltage.
- 3) Feed 150 VDC to the plate circuit.
- 4) Increase the filament voltage until the plate current reads about 67 mA. Use the fine voltage control to increase the filament voltage until the plate current reads 70 mA.
- 5) Allow a 10-minute stabilization period during which time the plate current will slowly drop a few mA as the tubes reach thermal equilibrium. Use the fine voltage control on the filament supply to keep the plate current near 70 mA.
- 6) After the 10-minute stabilization period, measurements of the RF noise output may be made. Continue using the fine voltage control on the filament supply to keep the plate current between 69.9 and 70.1 mA. This is not difficult after that stabilization period. Typical stable values are:

Filament: 5.15 VDC @ 3.078 A \pm 10 mA

Plate: 150 VDC @ 70.0 \pm 0.1 mA

NOTE: While the Sylvania manual recommends keeping the maximum on period in a 50% duty cycle to no more than 5 minutes, the unit has been operated for up to an hour at a time with no apparent detrimental effects. However, it is possible that this may shorten tube life, so extended periods of operation should be avoided when possible. The Sylvania manual indicates a tube life of about 100 hours when the filaments are operated at 5.15 volts.

Shut down:

- 1) Turn off the DC plate supply.
- 2) Turn the filament supply voltage down to zero and then turn it off.

Noise diodes 5722 calibrator

(Translation of Appendix A of F. Reyes Univ. of Chile thesis "Radiotelescopio en 45 MHz para Fuentes Extragalacticas, 1977)

In order to determine the absolute power received by a radio telescope it is necessary to have of a source that provide a signal of a known power, so it can be used as a calibrator. Since the signal received by the antenna has the characteristic of noise, it is required that the calibrator has the same characteristics.

A resistor at the absolute temperature T generates a noise power W that can be calculated by

$$W = kT\Delta v \quad (1)$$

Where k is the Boltzmann constant and Δv is the bandwidth

In radio astronomy and in particular at low frequencies the antenna temperatures are of the order of several thousand K. This makes impossible to obtain a source of noise of the required power from the noise produced by a resistor.

For the frequency range of 1 to 1000 MHz, it is accepted as a standard noise source, the saturated diodes limited by temperature.

The quadratic mean value of the noise current i_n^2 for these diodes is given by the relationship

$$i_n^2 = 2eI\Delta v \quad (2)$$

Where e is the charge of the electron ($1,6 \cdot 10^{-19}$ coulombs) and I is the plate DC current of the diode

These diodes are essentially a source of noise current. It is necessary to define the noise power delivered by the diodes by defining the impedance over which the noise current circulate. Figure 1 is a simplified schematic of the circuit of a noise diode.

Figure 1. Simplified schematic of the circuit of a noise diode

R_L is the load resistor (of value equal to R), R is the resistor that define the power delivered by the diode, C a capacitor to isolate R from the DC plate voltage and L is an inductance to keep the noise power from reaching the DC plate voltage source.

The noise power available at the terminals AB is

$$W = (\frac{1}{2}i_n)^2 R \quad (3)$$

(3) The power can be expressed as function of temperature by combining equations (1) and

$$kT\Delta v = (\frac{1}{2}i_n)^2 R$$

Rearranging this equation and substituting by equation (2) we get

$$T = eIR/2k$$

To this noise temperature T one has to add the contribution of noise due to the ambient temperature T_o of the resistor R .

The equation becomes

$$T_g = T_o + eIR/2k \quad (4)$$

This equation shows that it is possible to determine the noise temperature of the diodes by measuring I , the DC plate current.

Substituting in equation (4) the values for $e = 1.6 \cdot 10^{-19}$ Coulombs, $k = 1.38 \cdot 10^{-23}$ Joule/K, $T_o = 290$ K, $R = 75$ ohms and expressing the current I in milliamps,

$$T = 434.78 I + 290 \text{ (in K)} \quad (5)$$

One of the diodes commonly used is the 5722. Some of the parameters of this diode are:

- Maximum plate current = 35 ma
- Plate voltage = 200 v
- Output capacitance = 2.2 pf
- Filament voltage = 6.3 v
- Filament current = 1.5 amps

Most calibrator used at radio observatories in the past make use of two 5722 diodes. Two diodes provides up to 70 ma DC current, which correspond to a noise temperature of 30,000 K. This standard calibrator can be used to calibrate other source noise such as the noisy amplifier HP 461 which can provide up to 60 million K of noise temperature which makes them useful for calibrating low frequency emission from Jupiter and the Sun.

CIRCUIT APPLICATION

Sylvania Type 5722 is a tungsten filament diode designed for use as a noise generator at frequencies up to 400 or 500 mc. The filament center tap allows better RF grounding of the filament when used in the recommended circuit shown on a following page.

Since the tube has a tungsten filament the "shot effect" may be used as a standard noise source if sufficient plate voltage is applied to obtain saturation. The noise factor (NF) may be obtained from the equation $NF = 20 IR$ where R is the total generator resistance and I is the diode plate current in amperes. To convert to decibels $NF_{db} = 10 \log_{10} 20 IR$.

In use, the diode is coupled to the input of the amplifier under test and the filament voltage is increased until the noise output power is double that read without the diode. From the plate current reading and the generator resistance the noise factor can be calculated. Additional construction details may be obtained from the article "How Sensitive is Your Receiver", by Byron Goodman in the September 1947 issue of Q.S.T. and also "Coaxial Noise Diode" by H. Johnson, RCA Review, March, 1947, Volume VIII, No. 1.

The useful life is dependent on the operating voltages since the usual causes of failure are burnout or vaporization of the tungsten filament. A curve is given on a following page which shows this relationship.
